Genus Characterizes the Complexity of Certain Graph Problems: Some Tight Results

Jianer Chen† Iyad A. Kanj‡ Ljubomir Perković‡ Eric Sedgwick‡ Ge Xia§

Abstract

We study the fixed-parameter tractability, subexponential time computability, and approximability of the well-known NP-hard problems: INDEPENDENT SET, VERTEX COVER, and DOMINATING SET. We derive tight results and show that the computational complexity of these problems, with respect to the above complexity measures, is dependent on the genus of the underlying graph. For instance, we show that, under the widely-believed complexity assumption \( W[1] \neq FPT \), INDEPENDENT SET on graphs of genus bounded by \( g_1(n) \) is fixed parameter tractable if and only if \( g_1(n) = o(n^\alpha) \), and DOMINATING SET on graphs of genus bounded by \( g_2(n) \) is fixed parameter tractable if and only if \( g_2(n) = n^{o(1)} \). Under the assumption that not all SNP problems are solvable in subexponential time, we show that the above three problems on graphs of genus bounded by \( g_3(n) \) are solvable in subexponential time if and only if \( g_3(n) = o(n) \). We also show that the INDEPENDENT SET, the kernelized VERTEX COVER, and the kernelized DOMINATING SET problems on graphs of genus bounded by \( g_4(n) \) have PTAS if \( g_4(n) = o(n/\log n) \), and that, under the assumption \( P \neq NP \), the INDEPENDENT SET problem on graphs of genus bounded by \( g_5(n) \) has no PTAS if \( g_5(n) = \Omega(n) \), and the VERTEX COVER and DOMINATING SET problems on graphs of genus bounded by \( g_6(n) \) have no PTAS if \( g_6(n) = n^{\Omega(1)} \).

1 Introduction

NP-completeness theory [24] serves as a foundation for the study of intractable computational problems. However, this theory does not obviate the need for solving these hard problems because of their practical importance. Many approaches have been proposed to solve these problems, including polynomial time approximation, fixed parameter tractable computation, and subexponential time algorithms. The INDEPENDENT SET, VERTEX COVER, and DOMINATING SET problems are among the celebrated examples of such problems. Unfortunately, these problems refuse to give in to most of these approaches. It is known [5] that none of them has a polynomial time approximation scheme unless \( P = NP \). It is also unlikely that any of them is solvable in subexponential time [27]. In terms of fixed parameter tractability, INDEPENDENT SET and DOMINATING SET do not seem to have efficient algorithms even for small parameter values [19].

* A preliminary version of this work was reported at The Thirtieth International Colloquium on Automata, Languages, and Programming (ICALP 2003), Eindhoven, The Netherlands, June 30–July 4, 2003, and published in Lecture Notes in Computer Science 2719, pp. 845-856, (2003). Table 1: Comparison between our results and the previous results

Variants of these problems were studied as well where the input graph is constrained to have certain structural properties (e.g., bounded degree graphs and planar graphs) [1, 3, 6, 20, 24]. In particular, the problems on the class of planar graphs (the problems remain NP-hard) become more tractable in terms of the above three complexity measures. All of the three problems on planar graphs have polynomial time approximation schemes [7, 30], and are solvable in subexponential time [30]. Recent research in fixed parameter tractability shows that all the three problems admit parameterized algorithms whose running time is subexponential in the parameter [3]. This line of research has attracted considerable recent interests and the results have been extended to graphs of bounded genus [16, 20, 23].

This raises an interesting question: What are the graph structures that determine the computational complexity of these important NP-hard problems?

In this paper, we demonstrate how the genus of the underlying graph plays an important role in characterizing the parameterized complexity, the subexponential time computability, and the approximability of the VERTEX COVER, INDEPENDENT SET, and DOMINATING SET problems. Our research shows that in most cases, graph genus is the sole factor that determines the complexity of the above problems. More precisely, in most cases, there is a precise genus threshold that determines the computational complexity of the problems in terms of the three complexity measures. For instance, we show that under the widely-believed complexity assumption $W[2] \neq \text{FPT}$, DOMINATING SET is fixed parameter tractable if and only if the graph genus is $n^{o(1)}$. This result significantly extends both Alber et al. and Ellis et al.’s results for planar graphs and for constant genus graphs [1, 20]. The proof is also simpler and more uniform. It is also shown that under the assumption $W[1] \neq \text{FPT}$, INDEPENDENT SET is fixed parameter tractable if and only if the graph genus is $o(n^2)$. For the subexponential time computability, we show that under the assumption that not all SNP problems are solvable in subexponential time, VERTEX COVER, INDEPENDENT SET, and DOMINATING SET are solvable in subexponential time if and only if the genus of the graph is $o(n)$. In terms of approximability, we show that graph genus has a direct impact on whether INDEPENDENT SET, VERTEX COVER, and DOMINATING SET have polynomial time approximation schemes. A summary of our main results and the previous known results is given in Table 1.

We make two remarks on our results. First, all our tractability results are robust [21] in the sense that our algorithms work correctly regardless of whether the input graphs satisfy the required genus bound $g(n)$. As long as the input graphs satisfy the required genus bound $g(n)$, our algorithms construct correct solutions for the problems; whereas when our algorithms fail in constructing a solution, they correctly report that the genus of the input graph exceeds the required bound $g(n)$. Second, the techniques proposed in the current paper are not restricted to only the above three problems, and can be extended to derive similar results for other NP-hard graph problems.
We give a quick review on the related terminologies. Let $G$ be a simple and undirected graph. A set of vertices $C$ is a vertex cover for $G$ if every edge in $G$ is incident to at least one vertex in $C$. An independent set $I$ in $G$ is a subset of vertices such that no two vertices in $I$ are adjacent. A dominating set $D$ in $G$ is a set of vertices such that every vertex in $G$ is either in $D$ or adjacent to a vertex in $D$. The vertex cover (resp. independent set, dominating set) problem is for a given graph $G$ to construct a vertex cover of minimum size (resp. an independent set of maximum size, a dominating set of minimum size).

A surface of genus $g$ is a sphere with $g$ handles in the 3-space [25]. A graph $G$ embedded in a surface $S$ is a continuous one-to-one mapping from the graph into the surface. The embedding is cellular if each component of $S - G$, which is called a face, is homeomorphic to an open disk [25]. In this paper, we only consider cellular graph embeddings. The size of a face is the number of edge sides along the boundary of the face. The (minimum) genus $\gamma_{\text{min}}(G)$ of a graph $G$ is the smallest integer $g$ such that $G$ has an embedding on a surface of genus $g$. For more detailed discussions on data structures and algorithms for graph embedding on surfaces, the readers are referred to [9].

2 Genus and Parameterized Complexity

Parameterized complexity theory [19] was motivated by the observation that many important NP-hard problems in practice are associated with a parameter whose value usually falls within a small or a moderate range. Thus, taking the advantage of the small size of the parameter may significantly speedup the computation. We briefly review the basic concepts and refer the readers to [19] for more details.

A parameterized problem consists of instances of the form $(x, k)$, where $x$ is the problem description and $k$ is an integer called the parameter. For instance, the vertex cover problem can be parameterized so that each instance of it is of the form $(G, k)$, where $G$ is a graph and $k$ is the parameter, asking whether the graph $G$ has a vertex cover of $k$ vertices. Similarly, we can define the parameterized versions for independent set and dominating set. A parameterized problem $Q$ is fixed parameter tractable if it can be solved by an algorithm of running time $f(k)n^c$, where $f$ is a function independent of $n = |x|$ and $c$ is a constant. Denote by FPT the class of all fixed parameter tractable problems. An example of the FPT problems is the vertex cover problem that can be solved in time $O(1.285^k + kn)$ [13]. On the other hand, a large class of computational problems seems not to belong to the class FPT. A hierarchy of parameterized intractability, the $W$-hierarchy, has been introduced [19]. The 0th level of the hierarchy is the class FPT, and the $i$th level is denoted by $W[i]$ for $i > 0$. A parameterized complexity preserving reduction (the fpt-reduction) has been defined as follows: a parameterized problem $Q$ is fpt-reducible to another parameterized problem $Q'$ if there is an algorithm of running time $f(k)|x|^c$ that on an instance $(x, k)$ of $Q$ produces an instance $(x', g(k))$ of $Q'$, such that $(x, k)$ is a yes-instance of $Q$ if and only if $(x', g(k))$ is a yes-instance of $Q'$, where the functions $f(k)$ and $g(k)$ depend only on $k$, and $c$ is a constant. A parameterized problem $Q$ is $W[i]$-hard if every problem in $W[i]$ is fpt-reducible to $Q$, and is $W[i]$-complete if in addition $Q$ is in $W[i]$. In particular, if any $W[i]$-hard problem is in FPT, then $W[i] = \text{FPT}$, which, to the common belief, is very unlikely.

2.1 Genus and Independent Set

The parameterized independent set problem (or simply independent set without any confusion) is a representative of the $W[1]$-complete problems [19]. Thus, it is unlikely to be fixed parameter tractable. Actually, very recent research has shown strong evidence that it is even un-
likely that the problem is solvable in time $n^{o(k)}$ [10, 11]. In this subsection, we discuss how graph genus affects the parameterized complexity of INDEPENDENT SET.

**Theorem 2.1** The INDEPENDENT SET problem on graphs of genus bounded by $g(n)$ is fixed parameter tractable if $g(n) = o(n^2)$.

**Proof.** Since $g(n) = o(n^2)$, there is a nondecreasing and unbounded function $r(n)$ such that $g(n) \leq n^2/r(n).$ Without loss of generality, we can assume that $r(n) \leq n^2$. Otherwise, $g(n) = 0$, and the theorem follows from [3]. Let $G$ be a graph of $n$ vertices and genus $g'(n)$. Recall that the chromatic number $\chi(G)$ of $G$ is the smallest integer $p$ such that $G$ can be colored with $p$ colors so that no two adjacent vertices are colored with the same color. By Heawood’s Theorem [25], the chromatic number $\chi(G)$ of the graph $G$ is bounded by $(7 + \sqrt{1 + 48g'(n)})/2$. From the definition, the chromatic number $\chi(G)$ of $G$ implies an independent set of at least $n/\chi(G)$ vertices in $G$. Thus, the size $\alpha(G)$ of a maximum independent set in the graph $G$ is at least $2n/(7 + \sqrt{1 + 48g'(n)})$. Since $g' \leq g(n) \leq n^2/r(n)$, we get (note that $r(n) \leq n^2$)

$$\alpha(G) \geq \frac{2n}{7 + \sqrt{1 + 48n^2/r(n)}} = \frac{2n\sqrt{r(n)}}{7\sqrt{r(n)} + \sqrt{r(n) + 48n^2}} \geq \frac{2n\sqrt{r(n)}}{7n + \sqrt{n^2 + 48n^2}} = \frac{\sqrt{r(n)}}{7}$$

(1)

Now we are ready for describing our parameterized algorithm. Note that one difficulty we must overcome is estimating the genus of the input graph. The graph minimum genus problem is NP-complete [32], and there is no known effective approximation algorithm for the problem. Therefore, some special tricks have to be used for this purpose. Here we will make use of the approximation algorithm for the graph minimum genus problem proposed in [12], which on an input graph $G$ constructs an embedding of $G$ whose genus is bounded by $\max\{4\gamma_{\min}(G), \gamma_{\min}(G) + 4n\}$. Consider the algorithm given in Figure 1.

**ALGORITHM. IS-FPT**

Input: a graph $G$ of $n$ vertices and an integer $k$

Output: decide if $G$ has an independent set of $k$ vertices

1. let $r_1(n) = \min\{r(n)/4, nr(n)/(n + 4r(n))\}$
2. construct an embedding $\pi(G)$ of $G$ using the algorithm in [12];
3. if the genus of $\pi(G)$ is larger than $n^2/r_1(n)$ then Stop (“the genus of $G$ is larger than $g(n)$”);
4. if $k \leq \sqrt{r_1(n)}/7$ then Stop (“the graph $G$ has an independent set of $k$ vertices”)

   else try all vertex subsets of $k$ vertices to derive a conclusion.

Figure 1: A parameterized algorithm for INDEPENDENT SET

We analyze the time complexity of the algorithm IS-FPT. First note that by our assumption on the function $r(n)$, the function $r_1(n)$ is also nondecreasing and unbounded. The embedding $\pi(G)$ of the graph $G$ in step 2 can be constructed in linear time [12], and the genus of the embedding $\pi(G)$ can also be computed in linear time [9].

Since $r_1(n) = \min\{r(n)/4, nr(n)/(n + 4r(n))\}$, if the genus $\gamma(\pi(G))$ of the embedding $\pi(G)$ is larger than $n^2/r_1(n)$, then $\gamma(\pi(G))$ is larger than both $4n^2/r(n)$ and $n^2/r(n) + 4n$. According to [12], the genus $\gamma(\pi(G))$ of the embedding $\pi(G)$ is bounded by $\max\{4\gamma_{\min}(G), \gamma_{\min}(G) + 4n\}$. Thus, in case $\gamma(\pi(G)) \leq 4\gamma_{\min}(G)$, we have $4\gamma_{\min}(G) > 4n^2/r(n)$, and in case $\gamma(\pi(G)) \leq \gamma_{\min}(G) + 4n$,
we have \( \gamma_{\text{min}}(G) + 4n > n^2/r(n) + 4n \). Thus, in all cases, we will have \( \gamma_{\text{min}}(G) > n^2/r(n) \geq g(n) \).

In consequence, the algorithm IS-FPT concludes correctly if it stops in step 3.

If the algorithm IS-FPT reaches step 4, we know that the minimum genus of the graph \( G \) is bounded by \( n^2/r_1(n) \). By the above analysis and the relation in (1), the size of a maximum independent set in \( G \) is at least \( \sqrt{r_1(n)}/7 \). Thus, in case \( k \leq \sqrt{r_1(n)}/7 \), there must be an independent set in \( G \) with \( k \) vertices. On the other hand, if \( k > \sqrt{r_1(n)}/7 \) then \( r_1(\sqrt{49k^2}) \geq n \), where \( r_1 \) is the inverse function of the function \( r_1(n) \) defined by \( r_1(p) = \min\{ q \mid r_1(q) \geq p \} \). Since the function \( r_1(n) \) is nondecreasing and unbounded, it is not difficult to see that the inverse function \( r_1^{-1}(p) \) is also nondecreasing and unbounded. Since enumerating all vertex subsets of \( k \) vertices in the graph \( G \) can be done in \( O(2^{n}) \) time, which is bounded by \( O(2^{r_1(49k^2)}) \), we conclude that the total running time of the algorithm IS-FPT is bounded by \( O(f(k) + n^2) \), where \( f(k) = 2^{r_1(49k^2)} \) is a function dependent only on \( k \) and not on \( n \).

Thus, the algorithm IS-FPT solves the INDEPENDENT SET problem on graphs of genus bounded by \( g(n) \) in time \( O(f(k) + n^2) \), and the problem is fixed parameter tractable.

\[ \square \]

**Remark.** The algorithm IS-FPT does not have to know whether the input graph has its minimum genus bounded by \( g(n) \). Moreover, the algorithm IS-FPT does not need to decide precisely whether the input graph has a minimum genus bounded by \( g(n) \). In fact, on some graphs whose minimum genus is larger than \( g(n) \), the algorithm IS-FPT may still be able to decide correctly whether the graphs have an independent set of size \( k \). The point is, if the input graph has its minimum genus bounded by \( g(n) \), then the algorithm IS-FPT, without needing to know this fact, will definitely and correctly decide whether it has an independent set of size \( k \).

**Theorem 2.2** The INDEPENDENT SET problem on graphs of genus bounded by \( g(n) \) is \( W[1] \)-complete if \( g(n) = \Omega(n^2) \).

**Proof.** Since INDEPENDENT SET on general graphs is \( W[1] \)-complete [19], it suffices to show that INDEPENDENT SET on general graphs is fpt-reducible to INDEPENDENT SET on graphs of genus bounded by \( g(n) \). Since \( g(n) = \Omega(n^2) \), we assume \( g(n) \geq cn^2 \), where \( c \) is a constant.

Let \( G_1 \) be an arbitrary graph with \( n_1 \) vertices. It is well-known that the genus \( g_1 \) of \( G_1 \) is always bounded by \( (n_1 - 3)(n_1 - 4)/12 \leq n_1^2/12 \) [25]. Thus, if \( c \geq 1/12 \) then \( G_1 \) already has its genus bounded by \( cn_1^2 \). Otherwise, we construct a new graph \( G_2 \) as follows. \( G_2 \) contains \( h = \lceil 1/(12c) \rceil \geq 1 \) copies of the graph \( G_1 \). Partition the \( h \) copies of \( G_1 \) arbitrarily into two nonempty groups \( A_1 \) and \( A_2 \), and pick any pair of adjacent vertices \( u_1 \) and \( v_1 \) in \( G_1 \). Now introduce a new edge \([u_2,v_2] \), where \( u_2 \) and \( v_2 \) are two new vertices. Connect \( u_2 \) to the vertex \( u_1 \) in each copy of \( G_1 \) in the group \( A_1 \) and connect \( v_2 \) to the vertex \( v_1 \) in each copy of \( G_1 \) in the group \( A_2 \). This completes the construction of the graph \( G_2 \). It is not difficult to verify that the graph \( G_1 \) has an independent set of \( k_1 \) vertices if and only if the graph \( G_2 \) has an independent set of \( k_2 = hk + 1 \) vertices. Thus, the reduction from \((G_1,k_1)\) to \((G_2,k_2)\) is an fpt-reduction. Moreover, the graph \( G_2 \) has \( n_2 = hn_1 + 2 \) vertices and we can verify [25] that the genus of \( G_2 \) is \( g_2 = hg_1 \). Thus, we have

\[
g_2 = hg_1 \leq \frac{hn_1^2}{12} = \frac{(hn_1)^2}{12h} \leq \frac{n_2^2}{12/(12c)} = cn_2^2 \leq g(n_2)
\]

Thus, the genus of the graph \( G_2 \) of \( n_2 \) vertices is bounded by \( g(n_2) \).

This completes the fpt-reduction that reduces an instance \((G_1,k_1)\) of INDEPENDENT SET on general graphs to an instance \((G_2,k_2)\) of INDEPENDENT SET on graphs of genus bounded by \( g(n) \). In consequence, INDEPENDENT SET on graphs of genus bounded by \( g(n) \) is \( W[1] \)-complete. 

\[ \square \]
Combining Theorem 2.1 and Theorem 2.2, and noting that the genus of a graph of \( n \) vertices is always bounded by \((n - 3)(n - 4)/12\) [25], we have the following tight result.

**Corollary 2.3** Assuming \( \text{FPT} \neq \text{W}[1] \), the independent set problem on graphs of genus bounded by \( g(n) \) is not fixed parameter tractable if and only if \( g(n) = \Theta(n^2) \).

### 2.2 Genus and Dominating Set

Dominating set is the most well-known \( W[2] \)-complete problem [19]. Thus, it is even “harder” than Independent Set in terms of its parameterized complexity. Recently, there has been considerable interest in developing parameterized algorithms for Dominating Set on graphs of small genus [1, 3, 16, 17, 20, 22, 23, 29]. In particular, it is known that Dominating Set on planar graphs [1, 3] and on graphs of constant genus [16, 17, 20, 23] is fixed parameter tractable. We will show a much stronger result in this subsection: Dominating Set on graphs of genus bounded by \( g(n) \) is fixed-parameter tractable if and only if \( g(n) = n^{o(1)} \).

For a given instance \((G, k)\) of Dominating Set, we apply a branch-and-bound process to construct a dominating set \( D \) of \( k \) vertices in \( G \). Initially, \( D = \emptyset \). In a more general form during the process, suppose we have correctly included certain vertices in the dominating set \( D \), and removed these vertices from the graph \( G \). The vertices in the remaining graph \( G' \) are colored either “white” or “black”, where each white vertex is adjacent to a vertex in \( D \) (thus needs no further domination) and each black vertex is adjacent to no vertex in \( D \) (thus still needs to be dominated in the remaining graph \( G'' \)). The graph \( G'' \) thus will be called a BW-graph. We call a set \( D' \) of vertices in the BW-graph \( G' \) a B-dominating set if every black vertex in \( G' \) is either in \( D' \) or is adjacent to a vertex in \( D' \). Note that if the current set \( D \) has \( d \) vertices, then the graph \( G \) has a dominating set of \( k \) vertices, including all vertices in \( D \), if and only if the BW-graph \( G'' \) has a B-dominating set of \( k - d \) vertices. Thus, our task is to construct a B-dominating set of \( k - d \) vertices in the BW-graph \( G'' \).

Certain reduction rules can be applied to a BW-graph \( G' \):

- **R1.** Remove from \( G' \) all edges between white vertices;
- **R2.** Remove from \( G' \) all white vertices of degree 1;
- **R3.** If all neighbors of a white vertex \( u_1 \) are neighbors of another white vertex \( u_2 \), remove \( u_1 \) from \( G' \).

Let \( G'' \) be a BW-graph after applying any of the above rules on \( G' \). It is known [1, 20] that there is a B-dominating set of \( k \) vertices in \( G' \) if and only if there is a B-dominating set of \( k \) vertices in \( G'' \). A BW-graph \( G \) is called reduced if none of the above rules can be applied. According to rule **R1**, every edge in a reduced BW-graph either connects two black vertices or connects a black vertex and a white vertex (the edge will be called a bb-edge or a bw-edge, respectively).

We will show that in a reduced BW-graph, the number of black vertices will not be very small. For this purpose, we first need to give a brief discussion on certain basic facts about graph embeddings. For more detailed and formal proofs of these facts, the readers are referred to [9].

**Fact 1.** A face of size 1 can only be made by a self-loop, and a face of size 2 must be made by two multiple edges on the same pair of vertices.

**Fact 2.** Let \( F \) be a face of size \( d \) in a graph embedding with boundary vertices \( u_1, u_2, \ldots, u_d \), cyclically ordered along the face boundary. If we run a new edge from \( u_i \) to \( u_i \) crossing the face \( F \), \( 1 \leq i \leq d \), then the face \( F \) is split into two faces of sizes \( i \) and \( d - i + 2 \), respectively, both having the new edge on their face boundaries. No other faces in the embedding are changed. Moreover, the embedding genus is unchanged.
Fact 3. In a given embedding of a graph $G$, the neighbors of every vertex $u$ in $G$ specify a unique cyclic order $[u_1, u_2, \ldots, u_d]$ so that the edges $[u, u_1]$, $[u, u_2]$, $\ldots$, $[u, u_d]$ form a cyclic order around the vertex $u$ in a small region on the embedding. In particular, if every triple $(u, u_i, u_{i+1})$, $i = 1, 2, \ldots, d$ (here we take $u_{d+1}$ as $u_1$), makes a triangle face on the embedding, then removing the vertex $u$ (and all edges incident on $u$) will merge all these triangle faces into a single face of size $d$. The embedding genus and all other faces are unchanged.

Fact 4. Suppose there is a triangle face $(u_1, u_2, u_3)$ in an embedding, the vertex $u_1$ has degree 2, and there are no multiple edges between $u_2$ and $u_3$, then removing the vertex $u_1$ and the two edges incident on $u_1$ neither changes the embedding genus nor creates a face of size less than 3.

The following lemma can be easily derived from the famous Euler Polyhedral Equation [25].

Lemma 2.4 If $G$ is a graph of $n$ vertices and $m$ edges (with possibly multiple edges and self-loops), and $G$ has an embedding on a surface of genus $g$ such that all faces of the embedding have size at least 3, then $m \leq 6g + 3n - 6$.

Now we are ready to prove the following important lemma, which derives relations among the numbers of black vertices, white vertices, edges, and the genus of a reduced BW-graph.

Lemma 2.5 Let $G$ be a reduced BW-graph of minimum genus $g$, with $m$ edges and $n$ vertices, in which $n_w$ are white and $n_b$ are black, and suppose that $G$ has neither multiple edges nor self-loops, then (a) $m \leq 9n_b + 18g - 18$; and (b) $n \leq 4n_b + 6g - 6$.

Proof. Let $\pi(G)$ be an embedding of genus $g$ for the graph $G$. By rules $R1$ and $R2$, the degree of a white vertex $u$ in $G$ is at least 2 and all neighbors of $u$ are black. We perform the following operations on each white vertex $u$.

If the white vertex $u$ has degree 2 with two black neighbors $u_1$ and $u_2$, and there is no edge between $u_1$ and $u_2$, then we add a new edge $[u_1, u_2]$ crossing a face in the embedding to make a triangle face with $u$ (note that since $u$ has degree 2, this is always possible). Adding the new edge $[u_1, u_2]$ does not create a face of size less than 3, because it does not introduce new self-loops or new multiple edges. Moreover, the embedding genus is unchanged.

If $u$ has degree $d > 2$ and $u_1, u_2, \ldots, u_d$ are the $d$ black neighbors of $u$, ordered in clockwise order around $u$ in the embedding, then for each pair of vertices $u_i$ and $u_{i+1}$, $i = 1, 2, \ldots, d$ (here we take $u_{d+1}$ as $u_1$), if the vertices $u_i$, $u_{i+1}$ do not form a triangle face in the embedding $\pi(G)$, then we add a new edge $[u_i, u_{i+1}]$, crossing a face in the embedding $\pi(G)$, to make a triangle face $(u_i, u_{i+1})$ (again, this is always possible). This does not change the embedding genus. Note that adding this new edge may create multiple edges between $u_i$ and $u_{i+1}$. However, the new edge does not create any faces of size less than 3. This can be proved as follows. First this does not create faces of size 1 because it does not create self-loops. Second, if it created a face of size 2, then the two sides of the new edge $[u_i, u_{i+1}]$ are on the face boundaries of a face of size 2 and a face of size 3 (i.e., the triangle face $(u, u_i, u_{i+1})$). This, according to Fact 2, would imply that before adding the new edge $[u_i, u_{i+1}]$, the vertices $u$, $u_i$, $u_{i+1}$ had already made a triangle face. This proves that adding the new edge $[u_i, u_{i+1}]$ does not create faces of size less than 3. Finally, note that the vertices $u_i$ and $u_{i+1}$ cannot be the neighbors of a white vertex of degree 2 – otherwise by rule $R3$, the white vertex of degree 2 would have been removed. Thus, processing white vertices of degree larger than 2 does not create multiple edges for white vertices of degree 2.

Since the graph $G$ has neither self-loops nor multiple edges, by Fact 1, the embedding $\pi(G)$ has all its faces of size at least 3. Let $G'$ be the graph and $\pi(G')$ be the embedding of $G'$ after applying the above process on all white vertices in $G$. By the above discussion, the embedding $\pi(G')$ has
genus \( g \) and all faces in \( \pi(G') \) have size at least 3. We estimate the number \( m_{bb} \) of bb-edges in the graph \( G' \). For each white vertex \( u \) of degree 2 with neighbors \( u_1 \) and \( u_2 \) in \( G' \), we associate the bb-edge \([u_1, u_2]\) with the two bw-edges \([u, u_1]\) and \([u, u_2]\). For each white vertex \( u \) of degree \( d > 2 \) with neighbors \( u_1, u_2, \ldots, u_d \) in \( G' \), for each \( i = 1, 2, \ldots, d \) (here we take \( u_{d+1} = u_1 \)), we associate the bb-edge \([u_i, u_{i+1}]\) that is on the boundary of the triangle face \((u, u_i, u_{i+1})\) with the bw-edge \([u, u_i]\). Note that each such bb-edge \([u_i, u_{i+1}]\) can be associated with at most two bw-edges because each edge can be on the boundaries of at most two faces. Moreover, the bb-edge \([u_i, u_{i+1}]\) cannot be associated with the two bw-edges incident on any degree-2 white vertex since \( u_i \) and \( u_{i+1} \) cannot be the neighbors of a degree-2 white vertex in \( G' \) (see the discussion in the last paragraph). Since every bw-edge must be incident on a white vertex, the above association shows that the number \( m_{bw} \) of bw-edges in the graph \( G' \) is at most twice of the number \( m_{bb} \) of bb-edges in \( G' \): \( m_{bw} \leq 2m_{bb} \). Since the bw-edges in the graph \( G' \) are the same as those in the graph \( G \), and the number of bb-edges in \( G' \) is no more than that in \( G' \), we obtain

\[ m \leq m_{bw} + m_{bb} \leq 3m_{bb} \]  

(2)

Moreover, since each white vertex in \( G \) has degree at least 2, it is easy to see that the number \( n_w \) of white vertices in \( G \) is at most half the number \( m_{bw} \) of bw-edges in \( G \). Thus,

\[ n_w \leq m_{bw}/2 \leq m_{bb} \]  

(3)

Recall that the embedding \( \pi(G') \) has genus \( g \) and all faces in \( \pi(G') \) have size at least 3. Now we remove all white vertices from the graph \( G' \) and from the embedding \( \pi(G') \). Let the resulting graph and embedding be \( G'' \) and \( \pi(G'') \), respectively. By Fact 3 and Fact 4, removing a white vertex neither changes the embedding genus nor creates faces of size less than 3. Thus, the embedding \( \pi(G'') \) has genus \( g \) and all faces in \( \pi(G'') \) have size at least 3. Note that the number of edges in \( G'' \) is equal to the number \( m_{bb} \) of bb-edges in \( G' \), and the number of vertices in \( G'' \) is equal to the number \( n_b \) of black vertices in \( G \). Applying Lemma 2.4 to the graph \( G'' \), we get

\[ m_{bb} \leq 6g + 3n_b - 6 \]

Replacing \( m_{bb} \) by \( 6g + 3n_b - 6 \) in relations (2) and (3), and noting that \( n = n_w + n_b \) complete the proof of the lemma. \( \square \)

Now we are ready to prove the following theorem.

**Theorem 2.6** The dominating set problem on graphs of genus bounded by \( g(n) \) is fixed parameter tractable if \( g(n) = n^{o(1)} \).

**Proof.** Since \( g(n) = n^{o(1)} \), we can write \( g(n) \leq n^{1/r(n)} \) for some nondecreasing and unbounded function \( r(n) \). For an instance \((G, k)\) of the dominating set problem, where the graph \( G \) has \( n \) vertices and genus \( g' \), we apply the algorithm DS-FPT in Figure 2.

Let \( \tau \) be the inverse function of the function \( r(n) \) defined by \( \tau(p) = \min \{ q \mid r(q) \geq p \} \). Then the function \( \tau \) is also nondecreasing and unbounded. In case \( k \geq \tau(n) \), we have \( \tau(k) \geq n \). Thus, step 1 of the algorithm DS-FPT takes time \( O(2^n) = O(2^{\tau(k)}) \).

Now suppose \( k < \tau(n) \), step 3 repeatedly branches at a black vertex of degree bounded by 19 in the reduced BW-graph \( G_0 \). The search tree size \( T(k) \) of step 3 thus satisfies the recurrence relation

\[ T(k) \leq 20 \cdot T(k - 1) \]
ALGORITHM. DS-FPT

Input: a graph $G$ of $n$ vertices and an integer $k$
Output: decide if $G$ has a dominating set of $k$ vertices

1. if $k \geq r(n)$ then solve the problem by enumerating all subsets of $k$ vertices in $G$; Stop;
2. $k_0 = k$; $D = \emptyset$; $G_0 = G$; color all vertices of $G_0$ black;
3. while there is a black vertex $u$ of degree $d \leq 19$ in $G_0$ do
   3.1. make a $(d + 1)$-way branch, each includes either $u$ or a neighbor of $u$ in $D$;
   3.2. remove the new vertex in $D$ from $G_0$, and color its neighbors in $G_0$ white;
   3.3. apply rules R1-R3 to make $G_0$ a reduced BW-graph;
   3.4. $k_0 = k_0 - 1$;
4. if the graph $G_0$ has at most $78n^{1/k}$ vertices
   4.1. then find a B-dominating set of $k_0$ vertices in $G_0$ by enumerating all vertex subsets
        of $k_0$ vertices in $G_0$
   4.2. else Stop (“the graph $G$ has genus larger than $g(n)$”);

Figure 2: A parameterized algorithm for DOMINATING SET

which has a solution $T(k) = O(20^k)$.

At the end of step 3, all black vertices in the reduced BW-graph $G_0$ have degree at least 20. Suppose at this point, the number of edges, the number of vertices, and the number of black vertices in $G_0$ are $m_0$, $n_0$ and $n_b$, respectively. Since $2m_0$ is equal to the sum of total vertex degrees in $G_0$, we have $2m_0 \geq 20n_b$. By Lemma 2.5(a), we also have $m_0 \leq 9n_b + 18g' - 18$ (note that the genus of the reduced BW-graph $G_0$ cannot be larger than the genus $g'$ of the original graph $G$). Combining these two relations, we get $n_b \leq 18g' - 18$. By Lemma 2.5(b), we have $n_0 \leq 4n_b + 6g' - 6$. Thus

$$n_0 \leq 4n_b + 6g' - 6 \leq 78g' - 78 < 78g'$$

Thus, if $g' \leq g(n) \leq n^{1/r(n)} < n^{1/k}$ (note $k < r(n)$), then the number $n_0$ of vertices in the graph $G_0$ must be bounded by $78n^{1/k}$. In this case, step 4.1 solves the problem in time $O(r_0^{k_0+1}) = O((n^{1/k})^k) = O(n)$. On the other hand, if $G_0$ has more than $78n^{1/k}$ vertices, then step 4.2 concludes correctly that the genus of the input graph $G$ is larger than $g(n)$.

In conclusion, the algorithm DS-FPT solves the DOMINATING SET problem on graphs of genus bounded by $g(n)$ in time $O(2^{f(k)} + 20^k + n)$, and the problem is fixed parameter tractable. □

We point out that the techniques used in Theorem 2.6 are simpler, more uniform, and derive much stronger results compared to the previous research, which was only valid for graphs of genus bounded by a constant [20]. Also, similarly to the algorithm IS-FPT, the algorithm DS-FPT does not have to know whether the input graph has minimum genus bounded by $g(n)$. For any graph of minimum genus bounded by $g(n)$, the algorithm will definitely derive a correct conclusion.

**Theorem 2.7** The DOMINATING SET problem on graphs of genus bounded by $g(n)$ is $W[2]$-complete if $g(n) = n^{\Omega(1)}$.

**Proof.** Since DOMINATING SET is $W[2]$-complete [19], it will suffice to show that DOMINATING SET on general graphs is fpt-reducible to the problem on graphs of genus bounded by $g(n)$. Since $g(n) = n^{\Omega(1)}$, we can assume that $g(n) \geq n^c$, where $c$ is a fixed constant.

Let $G_1$ be an arbitrary graph of $n_1$ vertices and genus $g_1$. As we indicated in the proof of Theorem 2.2, $g_1 \leq n_1^2$. We construct a new graph $G_2$, which is the graph $G_1$, plus $n_1^{2/c} - n_1$ new vertices $u, v$, and $v_i$, $i = 1, 2, \ldots, n_1^{2/c} - n_1 - 2$, where $u$ has degree 2 and is connected to the vertex $v$ and to an arbitrary vertex in the graph $G_1$, and $[v, v_i], i = 1, 2, \ldots, n_1^{2/c} - n_1 - 2$, make
a star centered at $v$. It is fairly easy to verify that the graph $G_2$ has $n_2 = n_1^{2/c}$ vertices and genus $g_2 = g_1$, and that the graph $G_1$ has a dominating set of $k_1$ vertices if and only if the graph $G_2$ has a dominating set of $k_2 = k_1 + 1$ vertices. Since $c$ is a constant, the reduction from $(G_1, k_1)$ to $(G_2, k_2)$ is an fpt-reduction. Moreover, since $g_2 = g_1 \leq n_1^2$, we have $g_2 \leq n_2^2 \leq g(n_2)$. Therefore, $(G_2, k_2)$ is an instance for DOMINATING SET on graphs of genus bounded by $g(n)$. This reduction proves that DOMINATING SET on graphs of genus bounded by $g(n)$ is $W[2]$-complete.

Combining Theorem 2.6 and Theorem 2.7, we derive the following tight result.

**Corollary 2.8** Assuming $\text{FPT} \neq W[2]$, the DOMINATING SET problem on graphs of genus bounded by $g(n)$ is fixed parameter tractable if and only if $g(n) = n^{o(1)}$.

### 3 Genus and subexponential time complexity

We say that a graph problem is solvable in sublinear exponential time (or shortly subexponential time) if it can be solved in time $2^{o(n)}$ on graphs of $n$ vertices. Very few NP-hard graph problems are known to be solvable in subexponential time. Lipton and Tarjan used their planar graph separator theorem to show that a class of NP-hard planar graph problems, including VERTEX COVER, INDEPENDENT SET, and DOMINATING SET, are solvable in subexponential time [30]. They also described how their results can be extended to graphs of constant genus [30]. Recently, deriving lower bounds on the precise complexity of NP-hard problems has been attracting more and more attention [8, 27, 10, 11]. In particular, Impagliazzo, Paturi, and Zane [27] introduced the concept of SERF-reduction and showed that many well-known NP-hard problems are SERF-complete for the class SNP [27, 31]. This implies that if any of these problems is solvable in subexponential time, then so are all problems in the class SNP, a consequence that seems quite unlikely.

In this section, we demonstrate how graph genus affects the subexponential time computability for VERTEX COVER, INDEPENDENT SET, and DOMINATING SET. Our algorithmic results in this section extend Lipton and Tarjan’s results on planar graphs and graphs of constant genus [30], and our lower bound results refine Impagliazzo, Paturi, and Zane’s results on general graphs [27].

**Proposition 3.1** ([18]) Let $G$ be a graph of $n$ vertices and genus $g$. There is a linear time algorithm that partitions the vertices of $G$ into three sets $A$, $B$, $C$, such that no edge joins a vertex in $A$ with a vertex in $B$, $|A||B| \leq n/2$, and $|C| \leq c_0 \sqrt{(g+1)n}$, where $c_0$ is a fixed constant.

**Theorem 3.2** The problems VERTEX COVER, INDEPENDENT SET, and DOMINATING SET on graphs of genus bounded $g(n)$ are solvable in subexponential time if $g(n) = o(n)$.

**Proof.** We first give a detailed description of our proof for DOMINATING SET. The idea is quite simple: we use Proposition 3.1 to partition the vertices of a given graph $G$ into the three sets $A$, $B$, and $C$, and enumerate all possible situations for the set $C$. Each fixed situation for the set $C$ splits the graph $G$ into two separated subgraphs, induced essentially by the vertex sets $A$ and $B$, respectively. Thus, we can recursively work on the two subgraphs independently. However, this must be done with care. In particular, in a given situation for the set $C$, if a vertex $u$ in $C$ is assigned to be not in the dominating set and $u$ is not adjacent to any vertex in $C$ that is assigned to be in the dominating set, then the vertex $u$ must remain in the graph and a vertex in $A$ or $B$ and adjacent to $u$ must be included in the dominating set in a later stage.

Thus, assuming recursively that a partial dominating set $D$ has been constructed, our recursive algorithm classifies the vertices in the remaining graph $G$ into five groups:
(1) dominating vertices, which are already included in the current $D$;
(2) dominated vertices, which should not be in $D$ and are adjacent to vertices in the current $D$;
(3) white vertices, which are adjacent to vertices in the current $D$ but are not yet decided whether to be in $D$;
(4) black vertices, which are not adjacent to any vertices in the current $D$ and are also not yet decided whether to be in $D$;
(5) red vertices, which should not be in $D$ but are not yet adjacent to any vertices in the current $D$.

The dominating vertices and dominated vertices will be removed from the graph. Thus, the remaining graph $G$ consists of only black, red, and white vertices (initially, $D = \emptyset$ and all vertices in $G$ are black). Such a graph $G$ will be called a BWR-graph. A BW-dominating set $D'$ in the BWR-graph $G$ is a set of black and white vertices in $G$ such that every vertex in $G$ is either in $D'$ or adjacent to a vertex in $D'$ (thus, a minimum BW-dominating set for the initial graph will be a regular minimum dominating set for the graph). To construct a minimum BW-dominating set for the BWR-graph $G$, we use Proposition 3.1 to partition the vertices of $G$ into the three vertex subsets $A$, $B$, and $C$. Then we consider all possible assignments on the vertices in the set $C$. Each vertex $u$ in $C$ has the following possible assignments:

- $u$ is a white vertex. Then either $u$ is in $D$ or $u$ is not in $D$;
- $u$ is a red vertex. Then $u$ must be dominated by a vertex in either $C$, or $A$, or $B$;
- $u$ is a black vertex. Then either $u$ is in $D$, or $u$ is not in $D$, and hence must be dominated by a vertex in either $C$, or $A$, or $B$.

An assignment to the vertices in $C$ can be as follows: each white vertex is assigned either “in-$D$” or “not-in-$D$”, each red vertex is assigned either “in-$A$” or “in-$B$”, and each black vertex is assigned either “in-$D$”, “in-$A$”, or “in-$B$”. After this assignment, a white vertex will become either a dominating vertex (if it is “in-$D$”) or a dominated vertex (if it is “not-in-$D$”); a red vertex adjacent to an “in-$D$” vertex in $C$ will become a dominated vertex (in this case, the assignment to the red vertex is ignored); a red vertex not adjacent to any “in-$D$” vertex in $C$ will become a red vertex and will be added to the set $A$ or $B$ (depending on whether it is an “in-$A$” or “in-$B$” vertex); an “in-$D$” black vertex will become a dominating vertex; a black vertex whose status is either “in-$A$” or “in-$B$” and is adjacent to an “in-$D$” vertex in $C$ will become a dominated vertex; finally, an “in-$A$” black vertex (resp. an “in-$B$” black vertex) not adjacent to any “in-$D$” vertex in $C$ will become a red vertex and will be added to the set $A$ (resp. $B$).

Let the subgraphs induced by the updated vertex sets $A$ and $B$ be $G_A$ and $G_B$, respectively (note that now $A$ and $B$ may contain some vertices that were originally in $C$). We then recursively work on the subgraphs $G_A$ and $G_B$. The algorithm is formally presented in Figure 3.

We analyze the algorithm. Suppose the original input graph $G_0$ has $n_0$ vertices. Set $b_0 = c_0 \sqrt{g(n_0)} + 1$, where $c_0$ is the constant given in Proposition 3.1 (the bound $b_0$ is fixed for all recursive calls to the algorithm $\text{DS-Solver}$). Suppose that the input to the algorithm $\text{DS-Solver}$ is a BWR-graph $G$ of $n$ vertices. If $\sqrt{n} < 6b_0$, then $n < 36c_0^2(g(n_0) + 1) = O(g(n_0))$, and a brute force method can construct a minimum BR-dominating set for $G$ in time $O(3^n) = O(3^O(g(n_0)))$. If $|C| > b_0 \sqrt{n}$, then $C$ would contain more than $c_0 \sqrt{(g(n_0) + 1)n}$ vertices. By Proposition 3.1, the graph $G$ would have genus larger than $g(n_0)$, which implies that the original input graph $G_0$ has genus larger than $g(n_0)$ (since $G$ is a subgraph of $G_0$). Thus, the algorithm stops correctly.
ALGORITHM. DS-Solver
Input: a BWR-graph $G$ of $n$ vertices, and a bound $b_0$
Output: a minimum BR-dominating set $D$ of $G$

1. if $\sqrt{n} < 6b_0$ then solve the problem by a brute force method; Stop;
2. partition the vertices of $G$ into the subsets $A$, $B$, $C$ as described in Proposition 3.1;
3. if $|C| > b_0\sqrt{n}$ then Stop(“the genus exceeds the bound”);
4. for each assignment to the vertices in $C$ do
   let $D$ be the set of vertices in $C$ that are assigned “in-D”;
   update the graph $G$ and the sets $A$ and $B$;
   construct the subgraphs $G_A$ and $G_B$;
   recursively construct the minimum BR-dominating sets $D_A$ for $G_A$ and $D_B$ for $G_B$;
   $D = D \cup D_A \cup D_B$;
5. output the smallest BR-dominating set constructed in step 4.

Figure 3: An algorithm solving DOMINATING SET

Thus, we have $\sqrt{n} \geq 6b_0$ and $|C| \leq b_0\sqrt{n}$. Since each vertex in $C$ can get at most 3 different assignments, the total number of different assignments to the set $C$ is bounded by $3^{|C|} \leq 3b_0\sqrt{n}$. Since originally, $|A|, |B| \leq n/2$, and the updated sets $A$ and $B$ are the original sets $A$ and $B$ plus some vertices in $C$, each of the subgraphs $G_A$ and $G_B$ contains at most $n/2 + b_0\sqrt{n} \leq 2n/3$ vertices (note that $b_0 \leq \sqrt{n}/6$). This gives the following recurrence relation for the time complexity $T(n)$ of the algorithm DS-Solver:

$$T(n) \leq 3^{b_0\sqrt{n}} \cdot 2T(2n/3) \leq 3^{b_0\sqrt{n}+1}T(2n/3) \quad \text{if} \quad \sqrt{n} \geq 6b_0$$
$$T(n) = O(3^{O(g(n_0))}) \quad \text{if} \quad \sqrt{n} < 6b_0$$

Solving this recurrence relation, we get $T(n) = O(3^{O(b_0\sqrt{n}+g(n_0))})$. In particular, if we let $n = n_0$ and replace $b_0$ by $c_0\sqrt{g(n_0)} + 1$, we get

$$T(n_0) = O(3^{O(c_0\sqrt{g(n_0)} + 1 \cdot \sqrt{n_0} + g(n_0))}) = 3^{O(\sqrt{n_0}g(n_0) + g(n_0))}$$

Thus, if $g(n_0) = o(n_0)$, then $T(n_0) = 2^{o(n_0)}$, and the algorithm DS-Solver solves the DOMINATING SET problem in subexponential time.

The subexponential time algorithms for VERTEX COVER and INDEPENDENT SET are similar, and actually simpler. For example, for VERTEX COVER, once we partition the input graph into three parts $A$, $B$, and $C$, each vertex $u$ in $C$ has only two possibilities: either in or not in the minimum vertex cover $W$. In case $u$ is in $W$, we simply remove $u$ from the graph; while in case $u$ is not in $W$, all neighbors of $u$ are forced to be in $W$, thus all neighbors of $u$, as well as $u$ itself, can be removed from the graph. Therefore, no vertices in $C$ will be added to the sets $A$ and $B$, and each of the induced subgraphs $G_A$ and $G_B$ will have at most $n/2$ vertices. This fact will simplify the analysis of the algorithm to derive the subexponential time bound. We leave the detailed verification to the interested readers.

Again we point out that our subexponential time algorithms for DOMINATING SET, VERTEX COVER, and INDEPENDENT SET work correctly without needing to know the precise genus value of the input graph. The algorithms either report correctly that the genus of the input graph exceeds the designated bound $g(n)$, or construct an optimal solution to the input graph.

Remark. After the publication of a preliminary version [14] of the current paper in 2003, there has been some further progress in this direction. Demaine et al. [16] developed an algorithm of
running time \(2^{O(gv^2 + g^2)}n^{O(1)}\) for the parameterized DOMINATING SET problem on graphs of genus bounded by \(g\), which was further improved by Fomin and Thilikos [23] who presented an algorithm of running time \(2^{O(\sqrt{fg} + g)} + n^{O(1)}\). Compared to the algorithm in [16], our algorithm in Theorem 3.2 is faster when the graph genus \(g\) is \(\Omega(\sqrt{n})\). Compared to the algorithm in [23], the running time of our algorithm (see Equality (4)) is of the same order as that of the algorithm in [23] for the general version (i.e., the non-parameterized version) of the DOMINATING SET problem (since the parameter \(k\) can be of order \(O(n)\)). Moreover, our algorithm seems much simpler (the algorithm in [23] uses the techniques of graph representativity and graph branch decomposition).

**Theorem 3.3** For any function \(g(n) = \Omega(n)\), if any of VERTEX COVER, INDEPENDENT SET, and DOMINATING SET on graphs of genus bounded by \(g(n)\) can be solved in subexponential time, then all problems in the class SNP can be solved in subexponential time.

**Proof.** Since \(g(n) = \Omega(n)\), we assume \(g(n) \geq cn\), where \(c\) is a fixed constant. Johnson and Szegedy [28] have shown that if INDEPENDENT SET on graphs of degree bounded by 3 is solvable in subexponential time then so is INDEPENDENT SET on general graphs, which, according to Impagliazzo, Paturi, and Zane [27], would imply that all problems in the class SNP are solvable in subexponential time. Therefore, for INDEPENDENT SET, it suffices to show that the problem on graphs of degree bounded by 3 is reducible to the problem on graphs of genus bounded by \(g(n)\) via a reduction that preserves the order of the number of vertices.

Let \(n_1, m_1, \text{ and } g_1\) be the number of vertices, the number of edges, and the genus of a graph \(G_1\) of degree bounded by 3. Then \(m_1 \leq 3n_1/2\), and by the Euler Polyhedral Equation [25], \(g_1 \leq (m_1 - n_1 + 1)/2 \leq (n_1 + 2)/4 \leq n_1/3\) for \(n_1 \geq 6\). If \(c \geq 1/3\), then \(G_1\) is already a graph of genus bounded by \(cn_1 \leq g(n_1)\). Thus, we assume \(c < 1/3\). We perform the following operation on the graph \(G_1\). Pick any edge in \(G_1\), and subdivide the edge by two degree-2 vertices. The resulting graph \(G'\) has \(n_1 + 2\) vertices and the same genus \(g_1\). Moreover, it can be proved [13, 15] that from any maximum independent set of \(G'\), a maximum independent set of \(G_1\) can be constructed in linear time. Therefore, if we apply this edge subdivision operation \([n_1/(6c) - n_1/2]\) times on the graph \(G_1\), we get a graph \(G_2\) of \(n_2\) vertices and genus \(g_2 = g_1\), where \(n_1/(3c) \leq n_2 \leq (3c + 1)n_1/(3c)\). Now since \(g_2 = g_1 \leq n_1/3 \leq cn_2\), the graph \(G_2\) of \(n_2\) vertices has genus bounded by \(g(n_2)\). The reduction is completed by observing that \(n_2 = O(n_1)\).

The theorem also holds for VERTEX COVER since INDEPENDENT SET can be reduced to VERTEX COVER using the same graph [24]. For DOMINATING SET, the theorem follows from the following facts: (1) VERTEX COVER on graphs of degree bounded by 3 can be reduced to DOMINATING SET on graphs of degree bounded by 6 [24]; and (2) subdividing an edge by three degree-2 vertices increases the minimum dominating set size by 1 [15] and does not change the graph genus. With these facts, the proof proceeds in a similar fashion to that for INDEPENDENT SET. We leave the details to interested readers.

The class SNP [31] contains many well-known NP-hard problems, including \(k\)-SAT, \(k\)-COLORABILITY, \(k\)-SET COVER, VERTEX COVER, and INDEPENDENT SET [27]. It is commonly believed that it is unlikely that all problems in SNP are solvable in subexponential time. Based on this, and combining Theorem 3.2 and Theorem 3.3, we have the following tight results.

**Corollary 3.4** Assuming that not all the problems in SNP are solvable in subexponential time, the VERTEX COVER, INDEPENDENT SET, and DOMINATING SET problems on graphs of genus bounded by \(g(n)\) are solvable in subexponential time if and only if \(g(n) = o(n)\).
4 Genus and approximability

We briefly review the related concepts and refer the readers to [6, 24] for more details. An optimization problem $Q$ is either a maximization or a minimization problem. Each instance $x$ of $Q$ is associated with a set of solutions and each solution $y$ for $x$ is associated with a value $f(x, y)$. For a given instance $x$ in $Q$, the objective is to find a solution with the maximum value $\max(x)$ (if $Q$ is a maximization problem) or the minimum value $\min(x)$ (if $Q$ is a minimization problem). An approximation algorithm $A$ for $Q$ is an algorithm that for each instance $x$ of $Q$ constructs a solution $A(x)$ for $x$. We say that the approximation ratio of the algorithm $A$ is bounded by $\rho$ if for all instances $x$ of $Q$, we have $\max(x)/f(x, A(x)) \leq \rho$ (if $Q$ is a maximization problem) or $f(x, A(x))/\min(x) \leq \rho$ (if $Q$ is a minimization problem). We say that an optimization problem $Q$ has a polynomial time approximation scheme, shortly PTAS, if for any constant $\epsilon > 0$, the problem $Q$ has a polynomial time approximation algorithm whose approximation ratio is bounded by $1 + \epsilon$. It is well-known that VERTEX COVER, INDEPENDENT SET, and DOMINATING SET on planar graphs have PTAS [7, 30].

**Proposition 4.1 ([18])** There is an $O(n \log g)$ time algorithm that for a given graph $G$ of $n$ vertices and genus $g$ constructs a subset $Z$ of at most $c \sqrt{gn} \log g$ vertices, where $c$ is a fixed constant, such that removing the vertices in $Z$ from $G$ results in a planar graph.

The algorithm in Proposition 4.1 does not need to know the genus of the input graph [18].

**Theorem 4.2** The INDEPENDENT SET problem on graphs of genus bounded by $g(n)$ has a PTAS if $g(n) = o(n/\log n)$.

**Proof.** Let $g(n) \leq n/(r(n) \log n)$, where $r(n)$ is a nondecreasing and unbounded function. Our PTAS for INDEPENDENT SET works as follows: for a given graph $G$ of $n$ vertices, we use the algorithm in Proposition 4.1 to construct the vertex subset $Z$ (this can be done in time $O(n \log n)$ even when the genus of $G$ is larger than $g(n)$). If the number $z_0$ of vertices in $Z$ is larger than $c \sqrt{g(n) n \log g(n)}$, then we know that the input graph $G$ has genus larger than $g(n)$ and we stop. Otherwise, the graph $G_1$ obtained by deleting the vertices in $Z$ from the graph $G$ is a planar graph. We apply any known PTAS algorithm (e.g., those given in [7, 30]) to construct an independent set $I_1$ for the graph $G_1$. We simply output $I_1$ as a solution to the original graph $G$.

It is obvious that this is a polynomial time approximation algorithm for INDEPENDENT SET on graphs of genus bounded by $g(n)$. What left is to analyze the approximation ratio of the algorithm. Because $g(n) \leq n/(r(n) \log n)$, the number of vertices $z_0$ in $Z$ is such that $z_0 \leq c \sqrt{g(n) n \log g(n)} \leq c n/\sqrt{r(n)}$. Let $n_1 = n - z_0$ be the number of vertices in the graph $G_1$. Let $\alpha$ and $\alpha_1$ be the sizes of a maximum independent set in the graphs $G$ and $G_1$, respectively. Then $\alpha_1 \leq \alpha \leq \alpha_1 + z_0$. Because $G_1$ is a planar graph, by the Four-Color theorem [25], $\alpha_1 \geq n_1/4$.

Let $\alpha'_1 = |I_1|$. Since the independent set $I_1$ is constructed by a PTAS on the planar graph $G_1$, $\alpha_1/\alpha'_1 \leq 1 + \epsilon$, where $\epsilon$ is the given error bound. Since the function $r(n)$ is nondecreasing and unbounded, there is a constant $N_0$ such that when $n \geq N_0$, we have

$$\frac{c}{4 \sqrt{r(n)}} \leq \frac{1}{8} \quad \text{and} \quad \frac{8c(1 + \epsilon)}{\sqrt{r(n)}} \leq \epsilon \quad (5)$$

From the first inequality, we get

$$\alpha'_1 \geq \frac{\alpha_1}{1 + \epsilon} \geq \frac{n_1}{4(1 + \epsilon)} = \frac{n - z_0}{4(1 + \epsilon)} \geq \frac{n - cn/\sqrt{r(n)}}{4(1 + \epsilon)}$$
\begin{align*}
\frac{1}{4(1+\epsilon)} - \frac{c}{4(1+\epsilon)\sqrt{r(n)}} &\geq \frac{n}{8(1+\epsilon)}.
\end{align*}

Since \(\alpha \leq \alpha_1 + z_0 \leq (1+\epsilon)\alpha_1' + \frac{cn}{\sqrt{r(n)}}\), combining this with (5) and (6), we get

\[
\frac{\alpha}{\alpha_1'} \leq 1 + \epsilon + \frac{cn}{\alpha_1'\sqrt{r(n)}} \leq 1 + \epsilon + \frac{8cn(1+\epsilon)}{n\sqrt{r(n)}} \leq 1 + 2\epsilon.
\]

Thus, the algorithm is a PTAS for INDEPENDENT SET on graphs of genus bounded by \(g(n)\).

Again our PTAS for INDEPENDENT SET does not need to know whether the input graph meets the given genus bound.

**Theorem 4.3** Assuming \(P \neq NP\), then INDEPENDENT SET on graphs of genus bounded by \(g(n)\) has no PTAS if \(g(n) = \Omega(n)\).

**Proof.** The proof uses techniques similar to those in Theorem 3.3, so we only give an outline of it. It is known that INDEPENDENT SET on graphs of bounded degree is APX-complete [6], which means that a PTAS for it would imply \(P = NP\) [5]. Now a graph \(G_1\) of \(n_1\) vertices and of bounded degree has its genus bounded by \(O(n_1)\). We can increase the number of vertices in \(G_1\) without changing the graph genus by subdividing the edges in \(G_1\) by degree-2 vertices (see the proof of Theorem 3.3). This will give a graph \(G_2\) of \(n_2\) vertices whose genus is bounded by \(g(n_2)\) (note that \(g(n) \geq cn\) for some constant \(c\)), and a PTAS for the graph \(G_2\) would imply a PTAS for the graph \(G_1\). In consequence, a PTAS for INDEPENDENT SET on graphs of genus bounded by \(g(n)\) would imply a PTAS for the same problem on graphs of bounded degree, which would imply that \(P = NP\).

Theorem 4.2 seems unlikely to hold for VERTEX COVER and DOMINATING SET. In fact, we can prove the following theorem.

**Theorem 4.4** Unless \(P = NP\), VERTEX COVER and DOMINATING SET on graphs of genus bounded by \(g(n)\) have no PTAS if \(g(n) = n^{\Omega(1)}\).

**Proof.** It is known that VERTEX COVER and DOMINATING SET on general graphs have no PTAS unless \(P = NP\) [5, 31]. Thus, it suffices to show how these problems on general graphs can be reduced to the ones on graphs of genus bounded by \(g(n) = n^{\Omega(1)}\). The proof is very similar to that for Theorem 2.7, thus we only give an outline of it. Consider the DOMINATING SET problem. For a given general graph \(G_1\) of \(n_1\) vertices, by attaching to \(G_1\) a very large star, we can construct a new graph \(G_2\) of \(n_2\) vertices, without changing the graph genus, such that the genus of the graph \(G_2\) is bounded by \(g(n_2)\), and that the domination numbers of the graphs \(G_1\) and \(G_2\) differ by exactly 1. Now a PTAS for the graph \(G_2\) would imply a PTAS for the graph \(G_1\). The theorem for VERTEX COVER can be proved using a similar construction.

On the other hand, we can derive results similar to Theorem 4.2 for VERTEX COVER and DOMINATING SET on “kernelized” graphs. Polynomial time kernelization algorithms have become an interesting topic in the recent research on NP-hard problems [2, 13, 23]. It has been demonstrated [26] that improvement on approximating VERTEX COVER and DOMINATING SET on kernelized graphs will directly imply the same improvement on approximating the problems on general graphs. In
the following, we discuss the impact of graph genus on the approximability of VERTEX COVER and DOMINATING SET on kernelized graphs.

We say that a graph $G$ of $n$ vertices is kernelized for the VERTEX COVER problem if the number of vertices in a minimum vertex cover for $G$ is at least $n/2$. Polynomial time kernelization algorithms have been developed [13, 26]. For an arbitrary graph $G$, the algorithms construct a kernelized graph $G'$, where a vertex cover $C'$ for the graph $G'$ gives directly a vertex cover $C$ for the graph $G$ that preserves the approximation ratio (that is, the ratio of $C$ to an optimal solution of $G$ is not worse than the ratio of $C'$ to an optimal solution of $G'$).

**Theorem 4.5** The VERTEX COVER problem on kernelized graphs of genus bounded by $g_1(n)$ has a PTAS if $g_1(n) = o(n/\log n)$. On the other hand, unless $P = NP$, the VERTEX COVER problem on kernelized graphs of genus bounded by $g_2(n)$ has no PTAS if $g_2(n) = \Omega(n)$.

**Proof.** The development of a PTAS for VERTEX COVER on graphs of genus bounded by $g_1(n) = o(n/\log n)$ is very similar to that for the PTAS for INDEPENDENT SET given in Theorem 4.2, except that for INDEPENDENT SET in Theorem 4.2, we used Four-Color theorem to derive a linear lower bound on the size of maximum independent sets for planar graphs, while for VERTEX COVER on kernelized graphs, the linear lower bound on the size of minimum vertex covers comes directly from the fact that the input graph is kernelized. To prove that VERTEX COVER has no PTAS on kernelized graphs of genus bounded by $g_2(n) = \Omega(n)$, we use the techniques given in the proof of Theorem 4.3, by observing that a graph obtained by applying the operations given in Theorem 3.3 (i.e., subdividing an edge by two degree-2 vertices [15]) on a kernelized graph is also kernelized. We leave the detailed verification to the interested reader.

Very recently, a kernelization algorithm for DOMINATING SET has been proposed. For a given graph $G$, let $\delta(G)$ be the size of a minimum dominating set in the graph $G$ and recall that $\gamma_{\min}(G)$ denotes the minimum genus of the graph $G$. Formin and Thilikos [23] proposed a polynomial time algorithm that reduces a given graph $G$ to a graph $G'$ such that $\delta(G) = \delta(G')$, and such that the number of vertices of $G'$ is bounded by $c_0(\delta(G') + \gamma_{\min}(G'))$, where $c_0 > 4$ is a constant. Based on this result, we can introduce the following definition: we say that a graph $G$ is kernelized for the DOMINATING SET problem if the number of vertices in $G$ is bounded by $c_0(\delta(G) + \gamma_{\min}(G))$, where $c_0$ is the constant given in [23].

**Theorem 4.6** The DOMINATING SET problem on kernelized graphs of genus bounded by $g_1(n)$ has a PTAS if $g_1(n) = o(n/\log n)$. On the other hand, unless $P = NP$, the DOMINATING SET problem on kernelized graphs of genus bounded by $g_2(n)$ has no PTAS if $g_2(n) = \Omega(n)$.

**Proof.** We only sketch the proof, which is similar to that for Theorem 4.5. We leave the detailed verification to the interested reader.

The PTAS for DOMINATING SET on kernelized graphs of genus bounded by $g_1(n) = o(n/\log n)$ is obtained in a similar way to the PTAS for VERTEX COVER given in Theorem 4.5, with the lower bound on the size of minimum dominating sets coming from the kernelization. To prove that DOMINATING SET has no PTAS on kernelized graphs of genus bounded by $g_2(n) = \Omega(n)$, we note that graphs of degree bounded by 3 are necessarily kernelized since the size of a minimum dominating set in such a graph is at least $n/4$ – each vertex can dominate at most 3 other vertices in the graph. Moreover, the genus of such a graph is bounded by $O(n)$ [25]. Therefore, the assumed PTAS for DOMINATING SET on graphs of genus bounded by $g_2(n)$ would imply a PTAS.
for dominating set on graphs of degree bounded by 3, which is APX-complete [6]. This, in consequence, would imply P = NP.

5 Final remarks

We have demonstrated how graph genus affects the computational complexity of the well-known NP-hard problems vertex cover, independent set, and dominating set in terms of the following complexity measures: the fixed parameter tractability, the subexponential time computability, and the polynomial time approximability. In most cases, we were able to derive a precise genus threshold that uniquely determines the computational complexity of the problems in terms of the complexity measures. Our algorithmic results significantly extend the previous research on the problems on planar graphs and on graphs of constant genus, while our complexity results refine the previous results on the problems and identify the “hardest graph instances” for the problems. It should be easy to see that our techniques and results can be extended to other NP-hard graph problems.

It is NP-hard to determine the minimum genus of a given graph [32]. However, it is interesting to point out that all the algorithms developed in this paper work correctly without needing to know whether the input graph exceeds the designated genus bound. Our algorithms either report correctly that the input graph exceeds the designated genus bound, or solve the problems correctly for the given graph. Our techniques seem to be useful for the study of other computational problems related to graph genus.

Our results on the fixed parameter tractability and on the subexponential time computability (sections 2 and 3) are tight. Our results on the polynomial time approximation schemes (section 4), however, have a gap between $o(n/\log n)$ and $\Omega(n)$ on the genus bound. According to [18], when the graph genus is $o(n)$, there is a set of $o(n)$ vertices whose removal results in a planar graph. However, no algorithm is known that efficiently constructs such a set. It should be interesting and seems to be possible to close the genus gap in section 4.

Our results show that a class of NP-hard graph problems, including some very well-known ones, becomes more tractable on lower genus graphs while becomes more intractable on higher genus graphs. It is interesting to compare our results to the results in [4], which shows that certain other NP-hard problems become more tractable on dense graphs, for which the graph genus is necessarily high. We notice that the problems studied in [4] are most graph cutting problems, such as Max-Cut, and Graph-Bisection, while problems studied in the current paper are vertex subset problems. A systematical study of the difference between these two kinds of NP-hard problems looks rather appealing.
